C: Basic Elements

C Program: Basic Elements

Preprocessor Directive

```
#include <stdio.h>
```

Main function

A C Program **always** start execution from this function

A function contains a number of **statements**

```
int main( )  
{
```

```
    int cur, prev1 = 1, prev2 = 1, i, n;
```

Variable Declaration

```
    n = 4;
```

```
    if( n <= 2 ){
```

```
        cur = 1;
```

```
    } else {
```

```
        for ( i = 3; i<=n; i++ ) {
```

```
            cur = prev1 + prev2;
```

```
            prev2 = prev1;
```

```
            prev1 = cur;
```

```
        }
```

```
    }
```

```
    printf("Answer is %d\n", cur);
```

```
    return 0;
```

```
}
```

C Variable

- Perhaps the first stumbling block for Python / JavaScript programmer
- **C Variable:**
 1. Must be **declared** before use
 2. Declaration must includes **data type**
 3. Do **not** have an initial value (i.e. cannot assume to be zero if uninitialized)

C Variable – Data Type

■ Data type dictates:

- [Obvious] The type of values stored in the variable
- [Not obvious] The **range** of values that can be stored
- [Not obvious] The **size** of the variable in memory

■ Common Data Types: *No need to memorise table 😊*

| Data Type | 32-bit Processor | 64-bit Processor |
|---------------------|---|---|
| <code>int</code> | Size: 4 bytes (32 bits) Range: -2^{31} to $2^{31}-1$ | Size: 8 bytes (64 bits) Range: -2^{63} to $2^{63}-1$ |
| <code>float</code> | Size: 4 bytes (32 bits) | Size: 8 bytes (64 bits) |
| <code>double</code> | Size: 8 bytes (64 bits) | Size: 16 bytes (128 bits) |
| <code>char</code> | Size: 1 byte (8 bit) Range: -2^7 to 2^7 | |

C: Limitations

① Range limitations

```
int i = 1;

while (i > 0) {
    i++;    //i.e. i = i + 1;
}
printf("What?!\\n");

return 0;
```

② Accuracy limitations

```
double d = 0;
int i;

for (i = 0; i < 10000; i++){
    d = d + 0.1;
}

printf("d is %.12f\\n", d);

return 0;
```

C: Data Type Conversion

- Hierarchy:

C: Data Type Conversion Rules

① Operations: $A \text{ op } B \rightarrow C$ (implicit)

- "lower" data types automatically promoted to match "higher" data type

- $2.0 / 5.0 \rightarrow 0.4$

$2.0 / 5 \rightarrow 0.4$ (5 promoted to 5.0)

② Assignment: $A = B$ (implicit)

- B promoted / demoted to match A

- `int myInt = 0.4;` // myInt stores 0

`double myDouble = 5` // myDouble stores 5.0

③ Type casting: (data type) (explicit)

- $(\text{double}) 2 / 5 \rightarrow 0.4$ (2 promoted to 2.0)
